# Minimax search

# Game trees

# Minimax

- ▶ Terminal game states have a **value**
  - ▶ E.g. +1 for a win, -1 for a loss, 0 for a draw
- ▶ I want to **maximise** the value
- ▶ My opponent wants to **minimise** the value
- ▶ Therefore I want to **maximise** the **minimum** value my opponent can achieve
- ▶ This is generally only true for **two-player zero-sum** games

# Minimax search

- ▶ Recursively defines a **value** for non-terminal game states
- ▶ Consider each possible “next state”, i.e. each possible move
- ▶ If it's my turn, the value is the **maximum** value over next states
- ▶ If it's my opponent's turn, the value is the **minimum** value over next states

# Minimax search pseudocode

```
procedure MINIMAX(state, currentPlayer)
  if state is terminal then
    return value of state
  else if currentPlayer = 1 then
    bestValue =  $-\infty$ 
    for each possible nextState do
       $v = \text{MINIMAX}(\text{nextState}, 3 - \text{currentPlayer})$ 
      bestValue = MAX(bestValue,  $v$ )
    end for
    return bestValue
  else if currentPlayer = 2 then
    bestValue =  $+\infty$ 
    for each possible nextState do
       $v = \text{MINIMAX}(\text{nextState}, 3 - \text{currentPlayer})$ 
      bestValue = MIN(bestValue,  $v$ )
    end for
    return bestValue
  end if
end procedure
```

# Stopping early

**for each** possible nextState **do**

$v = \text{MINIMAX}(\text{nextState}, 3 - \text{currentPlayer})$

$\text{bestValue} = \text{MAX}(\text{bestValue}, v)$

**end for**

- ▶ State values are always between  $-1$  and  $+1$
- ▶ So if we ever have  $\text{bestValue} = 1$ , we can stop early
- ▶ Similarly when minimising if  $\text{bestValue} = -1$

# Using minimax search

- ▶ To decide what move to play next...
- ▶ Calculate the minimax value for each move
- ▶ Choose the move with the maximum score
- ▶ If there are several with the same score, choose one at random

# Minimax for larger games

- ▶ The game tree for noughts and crosses has only a few thousand states
- ▶ Most games are too large to search fully, e.g. chess has  $\approx 10^{47}$  states
- ▶ Later we will look at **heuristics** and **pruning** to cut down the size of the tree
